

1. The first step is to identify the variables that are being measured. In this case, the variables are the number of hours worked per week and the number of hours spent on household chores per week.

2. The second step is to determine the units of measurement for each variable. For the number of hours worked per week, the unit is hours. For the number of hours spent on household chores per week, the unit is also hours.

3. The third step is to collect data for each variable. This can be done by asking respondents to report the number of hours they work per week and the number of hours they spend on household chores per week.

4. The fourth step is to analyze the data. This can be done by calculating the mean, median, and standard deviation for each variable.

5. The fifth step is to interpret the results. This can be done by comparing the results to previous studies or to theoretical expectations.
